Nonnegative Matrix Factorization (NMF)

Dimensionality reduction

- K, N typically much larger than R (maximal rank)
- Example: $N = 1000, K = 500, R = 20$
 $K \times N = 500,000, K \times R = 10,000, R \times N = 20,000$

Nonnegative Matrix Factorization (NMF)

Nonnegativity:

- Prevents mutual cancellation of template vectors
- Encourages semantically meaningful decomposition

NMF Optimization

Optimization problem:

Given $V \in \mathbb{R}_{\geq 0}^{K \times N}$ and rank parameter R minimize

$$\|V - WH\|^2$$

with respect to $W \in \mathbb{R}_{\geq 0}^{K \times R}$ and $H \in \mathbb{R}_{\geq 0}^{R \times N}$.

Optimization not easy:

- Nonnegativity constraints
- Nonconvexity when jointly optimizing W and H

Strategy: Iteratively optimize W and H via gradient descent

NMF Optimization

Computation of gradient with respect to H (fixed W)

$$D := RN$$

$$\varphi^W : \mathbb{R}^D \rightarrow \mathbb{R}$$

$$\varphi^W(H) := \|V - WH\|^2$$

$$\rho \in [1 : R]$$

$$v \in [1 : N]$$

NMF Algorithm

Lee, Seung: Algorithms for Non-Negative Matrix Factorization, Proc. NIPS, 2000.

Algorithm: NMF ($V \approx WH$)

Input: Nonnegative matrix V of size $K \times N$

Rank parameter $R \in \mathbb{N}$

Threshold ϵ used as stop criterion

Output: Nonnegative template matrix W of size $K \times R$

Nonnegative activation matrix H of size $R \times N$

Procedure: Define nonnegative matrices $W^{(0)}$ and $H^{(0)}$ by some random or informed initialization. Furthermore set $\ell = 0$. Apply the following update rules (written in matrix notation):

- $H^{(\ell+1)} = H^{(\ell)} \odot \left(\frac{(W^{(\ell)})^T V}{(W^{(\ell)})^T W^{(\ell)} H^{(\ell)}} \right)$
- $W^{(\ell+1)} = W^{(\ell)} \odot \left(\frac{V (H^{(\ell+1)})^T}{W^{(\ell)} H^{(\ell+1)} (H^{(\ell+1)})^T} \right)$
- Increase ℓ by one.

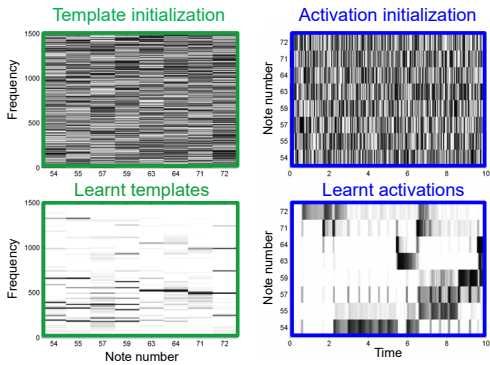

Repeat the steps (1) to (3) until $\|H^{(\ell)} - H^{(\ell-1)}\| \leq \epsilon$ and $\|W^{(\ell)} - W^{(\ell-1)}\| \leq \epsilon$ (or until some other stop criterion is fulfilled). Finally, set $H = H^{(\ell)}$ and $W = W^{(\ell)}$.
